fodder trees and fodder shrubs have always played a significant role in feeding domestic animals in fact trees and shrubs are increasingly recognized as important components of animal feeding particularly as suppliers of protein and especially in harsh environmental conditions in such situations the available grazing is not generally sufficient to meet the maintenance requirements of animals at least for part of the year this occurs for example in some mountainous regions and in the dry tropics where the grazing is also sometimes very degraded thus in extensive animal production systems in the dry areas of africa it is generally estimated that ligneous materials contribute up to 90 of production and account for 40 50 of the total available feed such figures illustrate the existing and urgent need not only for better knowledge but also for better use of such potential particularly in the context of environmental degradation which is affecting our planet on the other hand in the humid tropics of latin america the south cast asia and africa fodders from trees and shrubs from leguminous species are beginning to be utilized more dietary nitrogen supplements for ruminants in this respect new a significant move to look for new sources of protein from shrubs however given the increasing demand for forage and availability of low quality basal feed materials which require protein supplementation high protein fodders from leguminous trees and shrubs could have a much more significant role in animal feeding systems throughout the developing world in this respect there is a need for more research to develop technically viable solutions these solutions must also be economically and socially acceptable they must preserve natural resources and protect the environment in other words the challenge is the sustainable development of fodder trees and shrubs
